# Therapeutic mechanisms of GLP1RAs on NASH

#### The milestone for GLP1RAs on NASH: the LEAN TRIAL

Liraglutide safety and efficacy in patients with non-alcoholic steatohepatitis (LEAN): a multicentre, double-blind, randomised, placebo-controlled phase 2 study

Methods This multicentre, double-blinded, randomised, placebo-controlled phase 2 trial was conducted in four UK medical centres to assess subcutaneous injections of liraglutide (1·8 mg daily) compared with placebo for patients who are overweight and show clinical evidence of non-alcoholic steatohepatitis. Patients were randomly assigned (1:1) using a computer-generated, centrally administered procedure, stratified by trial centre and diabetes status. The trial was designed using A'Hern's single-group method, which required eight (38%) of 21 successes in the liraglutide group for the effect of liraglutide to be considered clinically significant. Patients, investigators, clinical trial site staff, and pathologists were masked to treatment assignment throughout the study. The primary outcome measure was resolution of definite non-alcoholic steatohepatitis with no worsening in fibrosis from baseline to end of treatment (48 weeks), as assessed centrally by two independent pathologists. Analysis was done by intention-to-treat analysis, which included all patients who underwent end-of-treatment biopsy. The trial was registered with ClinicalTrials.gov, number NCT01237119.

Findings Between Aug 1, 2010, and May 31, 2013, 26 patients were randomly assigned to receive liraglutide and 26 to placebo. Nine (39%) of 23 patients who received liraglutide and underwent end-of-treatment liver biopsy had resolution of definite non-alcoholic steatohepatitis compared with two (9%) of 22 such patients in the placebo group (relative risk  $4 \cdot 3$  [95% CI  $1 \cdot 0 - 17 \cdot 7$ ]; p= $0 \cdot 019$ ). Two (9%) of 23 patients in the liraglutide group versus eight (36%) of 22 patients in the placebo group had progression of fibrosis ( $0 \cdot 2$  [ $0 \cdot 1 - 1 \cdot 0$ ]; p= $0 \cdot 04$ ). Most adverse events were grade 1 (mild) to grade 2 (moderate) in severity, transient, and similar in the two treatment groups for all organ classes and symptoms, with the exception of gastrointestinal disorders in 21 (81%) of 23 patients in the liraglutide group and 17 (65%) of 22 patients in the placebo group, which included diarrhoea (ten [38%] patients in the liraglutide group vs five [19%] in the placebo group), constipation (seven [27%] vs none), and loss of appetite (eight [31%] vs two [8%]).

	Liraglutide	Placebo	Relative risks or mean changes (95% CI) from baseline to 48 weeks (liraglutide vs placebo)	p value*
Primary outcome				
Number of patients with paired liver biopsies	23	22		
Patients with resolution of non-alcoholic steatohepatitis	9 (39%)	2 (9%)	4-3 (1-0 to 17-7)	0-019
Changes from baseline in hist	opathological pa	rameters		
Total NAFLD activity score				
Change in score	-1-3 (1-6)	-0-8 (1-2)	-0.5 (-1.3 to 0.3)	0.24
Patients with improvement	17 (74%)	14 (64%)	1.2 (0.8 to 1.7)	0-46
Hepatocyte ballooning score				
Mean change	-0.5 (0.7)	-0-2 (0-6)	-0·3 (-0·7 to 0·1)	0.15
Patients with improvement	14 (61%)	7 (32%)	1.9 (1.0 to 3.8)	0.05
Steatosis				
Change in score	-0.7 (0.8)	-0-4 (0-8)	-0-2 (-0-6 to 0-2)	0-32
Patients with improvement	19 (83%)	10 (45%)	1·8 (1·1 to 3·0)	0.009
Lobular inflammation				
Change in score	-0-2 (0-6)	-0-2 (0-5)	-0.01 (-0.3 to 0.3)	0.97
Patients with improvement	11 (48%)	12 (55%)	0-9 (0-5 to 1-6)	0.65
Kleiner fibrosis stage				
Change in score	-0.2 (0.8)	0.2 (1.0)	-0-4 (-0-8 to 0-1)	0.11
Patients with improvement	6 (26%)	3 (14%)	1.9 (0.5 to 6.7)	0-461
Patients with worsening	2 (9%)	8 (36%)	0·2 (0·1 to 1·0)	0-041

Data are n (%) or mean (SD). The mean of the two independent pathologists' scores for overall non-alcoholic fatty liver disease (NAFLD) activity score, steatosis, ballooning, inflammation, and fibrosis were used to compare the two treatment groups. The pathologists' agreement for overall NAFLD activity score using a weighted kappa was 0-854. \*p values and mean changes from baseline were calculated by linear regression analysis using the baseline characteristic score and treatment as model covariates (equivalent to ANCOVA); for categorical comparisons, p values were determined by <u>z</u>' analysis. fp value was determined by Fisher's exact test.

Table 2: Changes in liver histology after 48 weeks of treatment

# Post-hoc analysis of semaglutide trials on liver enzymes and markers of inflammation

#### Weight management trial (NCT02453711):

957 subjects from a phase 2, randomised, double-blind, multinational, placebo- and active-controlled dose-finding trial of semaglutide in combination with both dietary and exercise counselling. Semaglutide was given once daily for 52 weeks at subcutaneous doses of 0.05, 0.1, 0.2, 0.3 or 0.4 mg to individuals with obesity of non-endocrine origin (body mass index ≥30 kg/m2) without diabetes.

#### Cardiovascular outcomes trial (SUSTAIN-6; NCT01720446): 3297 subjects from a phase 3, randomised, double-blind, multinational, placebo-controlled trial of semaglutide given for the treatment of type 2 diabetes. Semaglutide was given once weekly at subcutaneous doses of 0.5 or 1.0 mg/week for 104 weeks to individuals at least 50 years of age with type 2 diabetes and a haemoglobin A1c level ≥7%, at high risk for, or with a prior history of, cardiovascular events and/or who had chronic kidney disease

# Post-hoc analysis of semaglutide trials on ALT levels

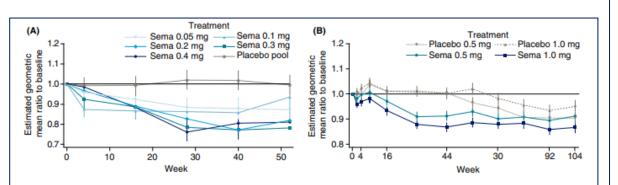

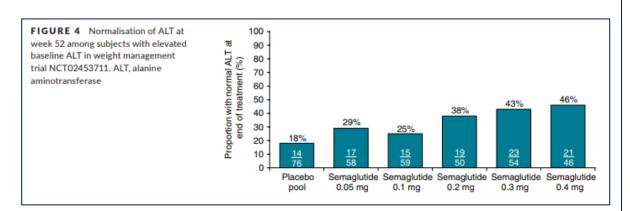

FIGURE 2 Estimated (mixed model for repeated measurements) mean ALT changes from baseline by treatment group and study visit for individuals with high baseline ALT in (A) weight management trial NCT02453711 and (B) cardiovascular outcomes trial SUSTAIN-6. ALT, alanine aminotransferase

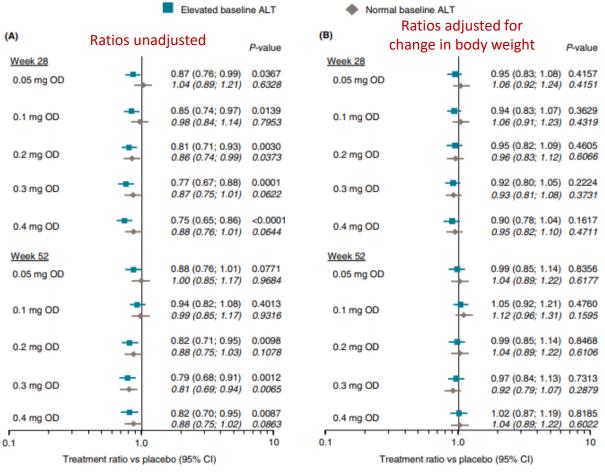

FIGURE 3 Treatment vs placebo ratios for change in ALT from baseline to weeks 28 or 52 in weight management trial NCT02453711 (A) unadjusted for change in body weight; and (B) adjusted for change in body weight. ALT, alanine aminotransferase; CI, confidence interval; OD, once daily

### Semaglutide and NASH: magnetic resonance imaging clinical trial

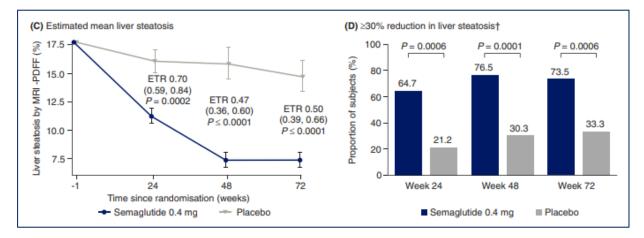

72-week randomised, double-blind, 1:1 placebocontrolled trial with once-daily subcutaneous semaglutide 0.4 mg (n = 34) or placebo (n = 33).

67 subjects with liver stiffness 2.50-4.63 kPa by magnetic resonance elastography (MRE) and liver steatosis  $\geq$ 10% by MRI proton density fat fraction (MRI-PDFF).

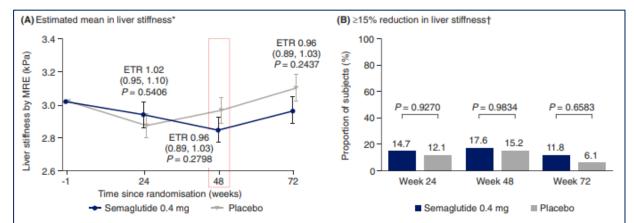

The primary endpoint was change from baseline to week 48 in liver stiffness assessed by MRE.

	Live	r biopsy	Liver biopsy	
		72 weeks treatment		

72-week, double-blind phase 2 trial involving patients with biopsyconfirmed NASH and liver fibrosis of stage F1-F2-F3.

320 patients were randomly assigned, in a 3:3:3:1:1:1 ratio, to receive once-daily subcutaneous semaglutide at a dose of 0.1, 0.2, or 0.4 mg or corresponding placebo.

The primary end point was resolution of NASH with no worsening of fibrosis. The confirmatory secondary end point was an improvement of at least one fibrosis stage with no worsening of NASH. (only for F2-F3 patients)

#### Semaglutide and NASH-CIRRHOSIS: phase 2 liver biopsy clinical trial

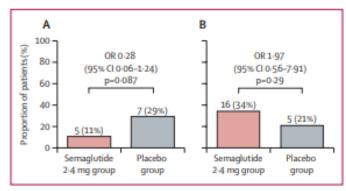

Semaglutide 2.4 mg once weekly in patients with non-alcoholic steatohepatitis-related cirrhosis: a randomised, placebo-controlled phase 2 trial

THE LANCET

48-week double-blind, placebo-controlled phase 2 trial.

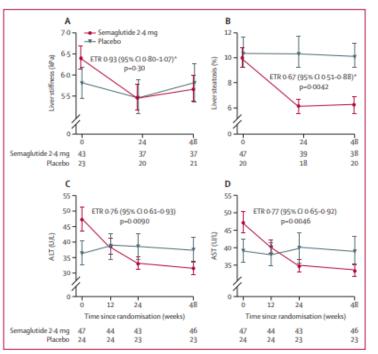

71 patients with compensated biopsy-confirmed NASHrelated cirrhosis and body-mass index (BMI) of 27 kg/m<sup>2</sup> or more were randomly assigned (2:1) to receive either once-weekly subcutaneous semaglutide 2.4 mg or placebo.

The <u>primary endpoint</u> was the proportion of patients with an improvement in liver fibrosis of one stage or more without worsening of NASH after 48 weeks.

#### Figure 2: Improvement in liver fibrosis and no worsening of NASH (A) and resolution of NASH (B) at 48 weeks

p-values are two-sided and taken from a Cochran-Mantel-Haenszel test stratified by baseline diabetes status. Patients with missing outcomes were imputed as non-responders. NASH=non-alcoholic steatohepatitis. OR=odds ratio.

Loomba et al. Lancet Gastroenterol Hepatol 2023; 8: 511-22

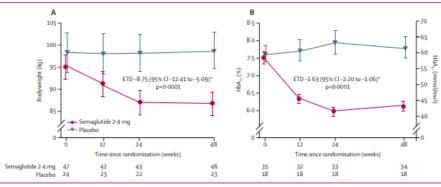

Figure 4: Change in (A) bodyweight and (B) HbA, (in patients with type 2 diabetes) from baseline to week 48 Number of observations per treatment group and visit is presented in the lower part of each plot. Error bas show the SE of the mean for observed values. ANCOVA-analysis of covariance. ETD-estimated treatment difference. "ETDs with 95% CI and two-sided p-values were calculated using the same ANCOVA analysis. Missing data were imputed from the observed data in the placebo group using the same ANCOVA model but without treatment as factor.

> In this phase 2 study of patients with NASH-related compensated cirrhosis, semaglutide 2.4 mg once weekly did not significantly improve fibrosis or achievement of NASH resolution compared with placebo. However, in patients with cirrhosis, semaglutide did lead to improvements in cardiometabolic risk parameters (weight loss, glycaemic control, and lipids), did not lead to new safety concerns, and was well tolerated based on the established profile of the GLP-1RA class. Despite the lack of histological changes with semaglutide, improvements were seen in non-invasive markers of disease activity. We also noted a clinically significant reduction in liver fat by MRI-PDFF.

### Semaglutide and NASH: ongoing phase 3 liver biopsy clinical trial

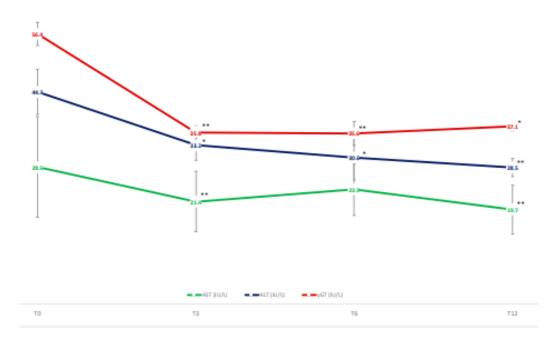

Research Study on Whether Semaglutide Works in People With Non-alcoholic Steatohepatitis (NASH) (ESSENCE) - ClinicalTrials.gov ID NCT04822181

- 1200 pts
- NASH with NAS  $\geq$ 4 and F2-3
- Semaglutide 2.4 mg/week vs. placebo
- 72 weeks: Resolution of steatohepatitis and no worsening of liver fibrosis; Improvement in liver fibrosis and no worsening of steatohepatitis
- 240 weeks: Time to first liver-related clinical event

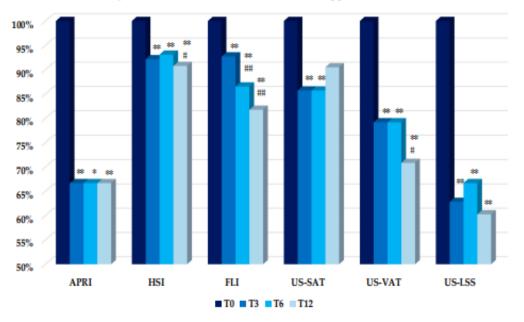

#### Semaglutide and NAFLD in real-life

#### Once-Weekly Subcutaneous Semaglutide Improves Fatty Liver Disease in Patients with Type 2 Diabetes: A 52-Week Prospective Real-Life Study

Changes in fibrotic and steatosis scores, and US appearance of NAFLD

### A glimpse into the future: COMBINATION THERAPY

Safety and efficacy of combination therapy with semaglutide, cilofexor and firsocostat in patients with non-alcoholic steatohepatitis: A randomised, open-label phase II trial

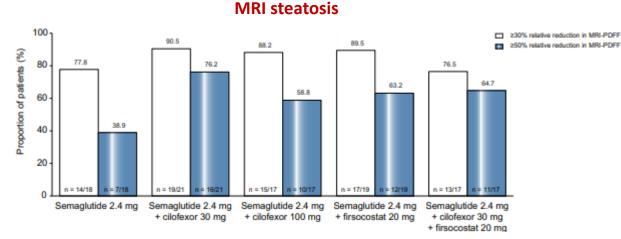

Phase II, open-label, proof-of-concept trial.

**108 patients with NASH** (F2–F3 on biopsy, or MRIproton density fat fraction [MRI-PDFF] >10% and liver stiffness by transient elastography >7 kPa) were randomised (1:1:1:1:1) to 24 weeks' treatment with semaglutide 2.4 mg once weekly as monotherapy or combination therapy with cilofexor 30 mg (SEMA + CILO 30), or cilofexor 100 mg (SEMA + CILO 100), or firsocostat 20 mg (SEMA + FIR) or cilofexor 30 mg plus firsocostat 20 mg (SEMA + CILO + FIR).

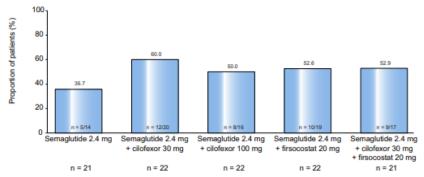

The primary endpoint was safety. All efficacy endpoints were exploratory

**<u>CILOFEXOR</u>**: non-steroidal agonist of farnesoid X receptor (FXR) that inhibits lipogenesis, gluconeogenesis and bile acid synthesis

**<u>FIRSOCOSTAT</u>**: acetyl-coenzyme A carboxylase (ACC) inhibitor that reduces hepatic de novo lipogenesis

#### Liver stiffness improvement (>25% relative reduction)

Alkhouri et al. Journal of Hepatology 2022;77:607–618

### A glimpse into the future: DUAL/TRIPLE INCRETINS AGONISTS

A phase IIa active-comparator-controlled study to evaluate the efficacy and safety of efinopegdutide in patients with non-alcoholic fatty liver disease

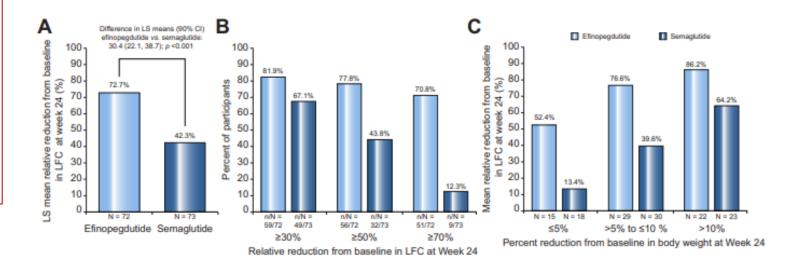

JOURNAL OF HEPATOLOGY

Phase IIa, randomized, active-comparator-controlled, parallel-group, open-label study.

**145 participants** with an MRI-PDFF liver fat content (LFC) of >10% at screening were randomized **1:1 to** efinopegdutide 10 mg or semaglutide 1 mg, both administered subcutaneously once weekly for 24 weeks.

The primary efficacy endpoint was **relative reduction from baseline in LFC (%)** after 24 weeks of treatment.

**EFINOPEGDUTIDE:** glucagon-like peptide-1 (GLP-1)/glucagon receptor co-agonist
